Connecting your website with Kigo

Contents

1 Process of connection

The process to connect your own website with Kigo consists in the following steps:

- We will provide you with a test account, named as your real account + TEST ACCOUNT to distinguish them. This test account will have some listings with fake data. You'll have the API credentials needed to work with this account, so you can use it to develop and test safely the integration of our APIs.

- Once you have completed the integration you need to pass a Certification:

    1. You must publish a couple of the shared test Listings and provide us with their URLs so we can check if their information is displaying correctly. It's preferable to done in a test environment if it's available.

    2. Then we'll start the tests (that could be adapted to your business model if needed), changing the static information, availability and prices while we check the API calls you're making to confirm you're making the right usage of the Diff endpoint and not making unnecessary calls.

    3. We will simulate the booking process, creating a new one and verifying the usage of the Kigo Checkout API usage and that the booking process is done properly.

    4. If we find something that is not working as intended, we will inform you about it, so you can correct it and go on with the Certification.

    5. We recommend a frequency of 5 minutes to make the API calls to get the **Diff** on availability, prices, content and status, we need to know if you're going to follow our recommendation or if you're planning to make the calls using a different frequency.

- Once you have passed the Certification, we will advise you, so you can stop publishing the Listings and we will provide you with the APIs credentials for your account so you can connect it with your website.
